8/2022 Diagnosis of uterine leiomyosarkoma with hepatic and peritoneal metastases: cT2NxM1

History of the disease:

- 9-12.2022: application of 4 courses of gemcitabine/docetaxel/avastine
- 9.2022: start with pazopanib, development of PRES
- 2.2023: application of yondelis planned, after 3-4 cycles restaging

27.2.23: Independent recommendation regarding further treatment options

- application of yondelis if at least stable disease after 3-4 cycles
- if progression, the combinatoin of doxorubicine plus DTIC should be considered - due to the better clinical data vs. doxorubicine mono
- ifosfamide should be avoied showing negative impact an PFS (and probably OS) by leiomyosarcoma in some retrospective data analysis
- off lable but potentially efficient could be the combination nivolumab/ipilimumab showing some promising disease stabilizations
